

Fig. 9.2 Typical fighter cockpit.

Civilian transports frequently have a much greater overnose vision angle, such as the Lockheed L-1011 with an overnose vision angle of 21 deg. Civilian overnose vision angles must be calculated for each aircraft based upon the ability of the pilot to see and react to the approach lights at decision height (100 ft {30.5 m}) during minimum weather conditions (1200-ft {366-m} runway visual range). The higher the approach speed, the greater the overnose vision angle must be.
